

Now that your system has been pumped here are some tips:

1. **We recommend that the system be refilled with fresh water once we leave.** We are unable to refill due to time constraints. This will help prevent floatation of tanks or implosion of tanks. Anytime a tank is pumped out it is under a stress that it normally does not have when at operating level.
2. All septic systems are designed for human waste. Refrain from putting trash such as food waste, baby wipes, feminine products or any other items that do not biodegrade in your sinks or toilets. More information can be found at www.texasseptic.com.
3. Our technician will be happy to answer any questions you may have about your septic system.
4. All systems are recommended to be pumped out on a routine schedule. Typically a conventional system is every five to seven years and an aerobic system every three to five years. This can vary depending on how the system is used, how many people live in the house and if tanks leak. The longer you wait the more potential issues you may have.
5. After an **aerobic system** is pumped you may get an air alarm. This is normal. The alarm should reset once your system is full again. We recommend you filling system until it is at operating level. This can take most of the day. **Conventional systems** are hard to tell when at operating level but you atleast need to turn on water for an hour or two.

Call us for all your future septic needs: We have Enzymes for you conventional septic system available and chlorine for your aerobic septic system.
